Abstract

Background: To assess species distribution and antifungal susceptibility of Candida isolates from cases of health-care associated infections in a tertiary care centre in central Kerala. Materials and Methods: Candida isolates from cases of HCAI from medical intensive care unit were identified up to species level. Antifungal susceptibility testing of Candida isolate was done by Clinical and Laboratory Standard Institute (CLSI) broth microdilution (BMD) method. Result: Out of 160 patients, males comprised 90 and females 70. Out of 60 patients on central line, 12 developed catheter related blood stream infection (CR-BSI), out of 55 patients, 22 developed catheter associated urinary tract infection (CA-UTI) and out of 45 patients on central line, 18 developed ventilator associated pneumonia. In 12 cases of CR-BSI, Klebsiella pneumoniae and C. krusei was found in 4 cases each, E. coli in 2, Pseudomonas aeruginosa and C. albicans in 1 case each. In 22 cases of CA-UTI, E. coli was found in 10, Klebsiella pneumoniae in 6, C. tropicalis in 3, Pseudomonas aeruginosa in 2 and C. krusei in 1 case. In 18 cases of VAP, Klebsiella pneumoniae was seen in 10, E. coli, Staphylococcus aureus and C. albicans in 2 cases each and Pseudomonas aeruginosa and C. krusei in 1 case each. The difference was significant (P< 0.05). Fluconazole resistance was significantly high in NAC spp. compared to C. albicans. All C. krusei isolates were resistant to fluconazole. A total of 20% of C. tropicalis were resistant to fluconazole. Resistance to itraconazole, voriconazole and amphotericin B was not observed in C. albicans. Amphotericin B resistance was observed in 20% of C. tropicalis. Conclusion: Fluconazole resistance was significantly high in non-albicans Candida spp. compared to C. albicans. Predominance of non-albicans Candida spp. over C. albicans was noted.

INTRODUCTION

Candida species is a normal flora in the human oral cavity with high carriage rate of more than 70%. Infections caused by Candida species are seen commonly in hospitalized patients. From the data obtained National Nosocomial Infections Surveillance (NNIS) system, U.S, out of the total fungal isolates associated with nosocomial infections, Candida species accounted for around 72%. Factors predisposing to this high frequency of yeast infections include: immunosuppressive conditions associated with chemotherapy, and stem cell and solid organ transplantations; prolonged hospitalisation; vascular catheterizations; and prolonged administration of broad spectrum antibacterial agents. Cross contamination by hospital personnel may also account for increase in yeast infections in certain environments. Oral candidiasis is widely seen among hospitalised patients and is considered as a sign of impaired local or systemic defense mechanisms.

Among various Candida species causing infections, C. albicans is regarded as the most prevalent one. But recently, non-albicans Candida (NAC) species are also emerging as pathogens. But
there is difference in pathogenicity and antifungal susceptibility among different species. In an ICU setting, *Candida* spp. accounts for nearly 10% of all bloodstream infections (BSI) and 25% of all urinary tract infections (UTIs).[3] In the United States, *Candida* spp. is 3rd or 4th common cause of health-care associated infections (HCAI), surpassing all Gram-negative bacilli. Nosocomial *Candida* infections are usually treatment resistant and are associated with prolonged hospitalization and increased healthcare-cost.[4]

The epidemiology of IC has significantly evolved in recent years. A progressive shift in the most common cause of infections from *Candida albicans* to non-albicans *Candida* spp. has been observed globally.[2] Antifungal resistance is also an increasingly difficult challenge for the implementation of effective empirical and prophylactic strategies, with emerging reports exhibiting resistance to multiple classes of antifungal agents.[5] Considering this, we performed present study to assess species distribution and antifungal susceptibility of *Candida* isolates from cases of health-care associated infections.

**MATERIALS AND METHODS**

After considering the utility of the study and obtaining approval from ethical review committee of the institute, we performed the present study in the Department of Microbiology, P K Das Institute of Medical Sciences. *Candida* isolates from 52 cases of healthcare associated infections (HCAI) from in-patients of a tertiary care centre during January 2021 to December 2021 were enrolled. The demographical and clinical features of the patients suspected for HCAI were recorded. *Candida* isolates were identified up to species by methods like KOH mount, Culture on Sabouraud’s Dextrose Agar, *Candida* CHROM agar & Corn Meal Agar and by Germ Tube test. Antifungal susceptibility testing of *Candida* isolate was done by Clinical and Laboratory Standard Institute (CLSI) broth microdilution (BMD) method. The minimum inhibitory concentration (MIC) of *Candida* spp was detected for antifungal drugs like Amphotericin B, Fluconazole, Itraconazole and Voriconazole. MIC values were determined as the lowest concentration of antifungal drug that showed complete inhibition or a significant diminution (≥50% inhibition) of growth compared to the growth of control strain. *Candida krusei* ATCC 6258 and *Candida parapsilosis* ATCC 22019 were used as control strains. The results were compiled and subjected for statistical analysis using Mann Whitney U test. P value less than 0.05 was set significant.

**RESULTS**

In 12 cases of CR-BSI, *Klebsiella pneumoniae* and *C. krusei* in was found 4 cases each, *E. coli* in 2, *Pseudomonas aeruginosa* and *C. albicans* in 1 case each. In 22 cases of CA-UTI, *E. coli* was found in 10, *Klebsiella pneumoniae* in 6, *C. tropicalis* in 3, *Pseudomonas aeruginosa* in 2 and *C. krusei* in 1 case. In 18 cases of VAP, *Klebsiella pneumoniae* was seen in 10, *E. coli*, *Staphylococcus aureus* and *C. albicans* in 2 cases each and *Pseudomonas aeruginosa* and *C. krusei* in 1 case each. The difference was significant (P< 0.05) [Table 3, Figure 1].

![Figure 1: Pathogens isolated from health-care associated infection](image-url)
Fluconazole resistance was significantly high in NAC spp. compared to C. albicans. All C. krusei isolates were resistant to fluconazole. A total of 20% of C. tropicalis were resistant to fluconazole. Resistance to itraconazole, voriconazole and amphotericin B was not observed in C. albicans. Amphotericin B resistance was observed in 20% of C. tropicalis [Table 4].

### DISCUSSION

In the ECDC point prevalence survey of healthcare-associated infections and antimicrobial use in European acute care hospitals 2011–2012, Candida spp. was the fifth most common pathogen associated with bloodstream infections, isolated in 7.4% of all documented cases. While C. albicans remains the predominant cause of invasive candidiasis, there has been a shift towards an increasing proportion of non-albicans Candida species such as C. glabrata in recent years. The present study was conducted to assess the species distribution and antifungal susceptibility of Candida isolates from cases of healthcare-associated infections.

Out of 160 patients, males comprised 90 and females 70. Out of 60 patients on central line, 12 developed catheter related blood stream infection (CR- BSI), out of 55 patients, 22 developed catheter associated urinary tract infection (CA- UTI) and out of 45 patients on central line, 18 developed ventilator associated pneumonia. Among, the candida species isolated, majority was non albicans Candida followed by Candida albicans. Shafi et al evaluated pattern of various Candida species among hospitalised patients with oral candidiasis, to detect the antifungal resistance among Candida and to assess the possible risk factors associated with those patients. Out of 300 patients screened, oral thrush material was collected from 36 patients having oral candidiasis. Candida spp. were isolated and identified. Antifungal susceptibility test was performed by disk diffusion method. Candida albicans was the most frequently isolated species (64%). Highest resistance was seen with ketoconazole (18%). Except one C. tropicalis, all the isolates were sensitive to amphotericin B. All the patients were on broad spectrum antibiotic treatment. Diabetes mellitus was seen in 50% of the patients. Other predisposing factors include tuberculosis, COPD, cancer and steroid treatment.

In 12 cases of CR- BSI, Klebsiella pneumoniae and C. krusei was found in 4 cases each, E. coli in 2, Pseudomonas aeruginosa and C. albicans in 1 case each. In 22 cases of CA- UTI, E. coli was found in 10, Klebsiella pneumoniae in 6, C. tropicalis in 3, Pseudomonas aeruginosa in 2 and C. krusei in 1 case. In 18 cases of VAP, Klebsiella pneumoniae was seen in 10, E. coli, Staphylococcus aureus and C. albicans in 2 cases each and Pseudomonas aeruginosa and C. krusei in 1 case each. Kamaljeet et al. assessed species distribution and antifungal susceptibility pattern of Candida isolates from cases of HCAI. Candida isolates from cases of HCAI from medical intensive care unit were identified and antifungal susceptibility testing of Candida isolates were done. The rate of CA-UTI due Candida spp. was 0.3 per 1000 catheter associated days. The rate of catheter related Candida BSI was 0.9 per 1000 catheter associated days. Predominance of non albicans Candida spp. over C. albicans was noted. Fluconazole resistance was significantly high in NAC spp. compared to C. albicans. All C. krusei isolates were resistant to fluconazole. A total of 20% of C. tropicalis were resistant to fluconazole. Resistance to itraconazole, voriconazole and amphotericin B was not observed in C. albicans. Amphotericin B resistance was observed in 20% of C. tropicalis [Table 4].
