INTRODUCTION

Third ventricle of brain is a narrow median cleft in the diencephalon between two thalami and communicates anteriorly to lateral ventricles through foramen of monro and posteriorly to fourth ventricle through narrow cerebral aqueduct, the cavity of midbrain. Blockage of cerebral aqueduct can lead to widening of third ventricle and accumulation of excess amount of CSF in 3rd and lateral ventricles leading to a condition known as hydrocephalus. [1,2] Third ventricle is related to many important brain structures including anterior commissure, fornix, tela choroidea, pineal body.
hypothalamic structures, optic chiasma, infundibulum, mammillary bodies, tegmentum of midbrain. Therefore it can be easily obstructed by brain tumors in these regions and thus cause hydrocephalus in infants and raised intracranial pressure in adults. Build up of pressure in third ventricle can also cause hypothalamic symptoms like diabetes insipidus and obesity.\[3,4\] There have been few studies which established a correlation between age and gender with the third ventricular morphometry. We require a normal range of ventricular dimensions in order to report size of the ventricle as abnormal. The study was undertaken with the specific purpose of obtaining a data regarding normal width of third ventricle in various age groups and to find out any gender disparity if present.

**MATERIALS AND METHODS**

It was an Observational study conducted in Department of Anatomy in collaboration with Department of Radiology and Department of Medicine at Era’s Lucknow Medical College and Hospital, Lucknow. All patients referred by Department of Medicine for MRI (Magnetic Resonance Imaging) were selected as study subjects on the basis of Inclusion / Exclusion Criteria.

**Inclusion Criteria**

Patients coming to medicine OPD with complain of recurrent headache, migraine, vertigo.

**Exclusion Criteria**

Subjects with lesions, malformations, masses, meningioma, colloid cyst or any other pathological problems were excluded.

**Sample Size**

Sample size was calculated on the basis of maximum variation in AP diameter of third ventricle, using the formula:

\[
  n = \frac{a \cdot \sigma^2 \cdot d^2}{\frac{1}{2}}
\]

Where, \( \sigma = 5.7 \), maximum value of SD
\( a=6 \), number of age group
\( s=2 \), number of sex (male and female)
Type 1 error \( \alpha=5\% \)
Allowable error \( d= 10\% \) of mean (31.33)
Data loss= 10%
Then sample size comes out to be
\( n=170 \)

**Methodology**

Informed consent was taken for the performing MRI on all study subjects. The machine used was APERTO 0.4 Tesla HITACHI. The parameters in this study were measured by marking two points and joining them by a straight line, on the MRI using DICOME method.\[5\] The study parameters included Age of the patient, Sex of the patient, Height of third ventricle, Transverse diameter and Antero-posterior diameter of third ventricle on MRI.

**Statistical Analysis**

Data so obtained were subjected to statistical analysis. Results were evaluated for the best modality through which benign and malignant lesions can be differentiated. Data analysis was done by SPSS software ® version 22.0. Descriptive statistical analysis, which included frequency and percentages, was used to characterize the data. Chi-square test was used for association between factors and \( p<0.05 \) was considered statistically significant. Correlation was used to find the relation.

**RESULTS**

As per [Table 1] in this, subjects were distributed almost in equal proportion among various age groups. However minimum proportion was observed in age < 2 year (7.6%) and maximum in the age groups 15 – 29 year (22.1%). In the study males were 57% while females were 43.0%. No significant association was seen (\( p>0.05 \)).

Table 1: Age and Gender wise distribution of study participants (N=170)

Table 2: Association of Age and Gender with AP, TRS and Height
As per Table 2 the mean TRS was 4.17±1.92 mm overall, 2.70±0.32 mm in males and 3.49±1.57 in females. The height was 13.61±3.65 mm overall, 11.13±4.45 mm in males and 12.47±4.07 in females. No significant difference between male & female was found in AP (p=0.476), TRS (p=0.090) and Height (p=0.292). Among the subjects of age 2-14 year, the mean AP was 18.60±6.26 mm overall, 18.48±6.85 mm in males and 18.76±5.65 in females. The mean TRS was 3.64±3.35 mm overall, 4.05±4.38 mm in males and 3.13±1.17 in females. The height was 13.42±4.22 mm overall, 13.81±5.24 mm in males and 12.94±2.52 in females.

The age of the study subjects showed significant positive correlation with AP (r=0.719, p=0.001) and TRS (r=0.348, p<0.001). However the correlation of age with height was not found to be significant (r=0.014, p=0.843) AP showed significant correlation with TRS (r=0.418, p<0.001) and height (r=0.291, p<0.001). TRS showed significant correlation with height (r=0.393, p<0.001) (A,B,C,D).
DISCUSSION

The ventricular system is a cavity of the brain, the two largest ventricles are the lateral ventricles in the cerebrum; the third ventricle is in the diencephalon of the forebrain between the right and left thalamus; and the fourth ventricle is located at the back of the Pons and upper half of the medulla oblongata of the hindbrain. Most of the morphometric studies on the effect of gender and age on the cerebral ventricles /brain ratio were carried out in western countries on the Caucasian population and a few studies were performed in the East Asian and Indian population. Although many of the studies in these areas have noted increments in lateral ventricle size associated with advancing age, few studies have addressed the issue of gender differences in this measure. Of those that have, two found no gender differences within an aged sample of normal (20% male subjects) and within a sample of schizophrenic subjects. Early studies utilizing linear measures found that men had larger lateral ventricular dimensions than women. A recent publication recommends controlling for skull size, which is reported to reduce the gender differences to statistically non significant levels. In another study carried out in 100 normal brain adults with Computed Tomography found that the left lateral ventricle was larger than right in both sexes and both lateral ventricles are larger in males. The linear measurement of lateral ventricles demonstrated positive correlation to cranial size while width of third ventricle was independent of size of the skull.

CONCLUSION

There exists a significant correlation between Antero-posterior and transverse diameter with age of an individual. No significant difference between male & female was found in AP (p=0.476), TRS (p=0.090) and Height (p=0.292). This study can be further extended by measuring third ventricle parameters in various pathological conditions like hydrocephalous, meningitis.
