INTRODUCTION

Nutrient foramen (foramina) are small openings present in the diaphysis of a long bone which allows blood vessels and nerves to supply the bone internal structure and helps in active bone growth.\cite{1} The major source of blood supply to the long bone is derived from nutrient artery supplemented by epiphyseal, metaphyseal and periosteal arteries.\cite{2-5}

The nutrient foramen will lead to the nutrient canal which extends into the medullary cavity of the bone. The nutrient foramen is always directed away from the growing end of the bone.\cite{6,7} All bones will have one or more nutrient artery which allows continuous nourishment to the bone and plays an important role in active growth of the bone.\cite{8-10}

The nutrient artery is very essential for the bone growth and development. Fracture to the bone may sometime lead to the rupture of the nutrient vessels. This might disrupt the blood supply to the bone thereby poor growth and development.\cite{11-15}

So, knowledge about the nutrient foramen is essential especially for microvascular surgery and orthopaedic surgeries, bone graft procedures and also in medico-legal cases. Knowledge of the nutrient foramen is also very important for Anatomist for proper teaching the importance of nutrient foramen to the first year MBBS students for clinical application.\cite{3,7}

Objectives

The study was conducted in the Department of Anatomy, Stanley Medical College, Chennai. The following objectives were studied,

1. Presence or absence of diaphyseal nutrient foramen in each bone.
2. Number of nutrient foramen.
3. Location of the nutrient foramen.
4. Direction of the nutrient foramen.

MATERIALS AND METHODS

This study was done in the Anatomy Dissection Hall in Government Stanley Medical College, Chennai. A total of 100 dry adult human humerus bone is taken for the study [Figure 1]. Bones were obtained from the Osteology lab of the Department of Anatomy. Among the 100 specimens, 53 belong to right side and 47 belong to left side. Bones with structural malformations and other deformities were excluded from the study.

Bones with diaphyseal nutrient foramen is studied for its presence, number, location and its direction.
The nutrient foramen is identified for its presence of groove which is usually well-defined. A 24-gauge needle is inserted into the nutrient foramen to check its patency. The presence, number, location and its direction were recorded and tabulated. Magnifying lens is used to identify the foramen. All the foramens noted are tagged, photographed, their landmark identified and documented.

**RESULTS**

Presence and Number of Foramen
Among the 100-humerus bone, 5 bones (2 from right side and 3 from left side) do not have nutrient foramen on its shaft (5%). Remaining 95% of the humerus showed presence of single or double foramen [Figure 2&3]. 91 bones showed single nutrient foramen (90.5% on right side and 91.4% on left side) and 4 bones showed double nutrient foramen (5.6% on right side and 2.1% on left side). No triple foramen is noted in all 100 specimens.

**Direction of nutrient foramen:**
Out of 95 nutrient foraminals, 94 foraminals (98.94%) were directed downward and one nutrient foramen (1.05%) were directed horizontally.

**DISCUSSION**

Among the Upper limb, Humerus bone receives the maximum blood supply. The nutrient artery to the humerus comes from branch of brachial artery. It is also supplied by branches of axillary, radial and ulnar arteries. The vasculature of the bone is very important in fracture healing. Since the majority of the humerus has single nutrient foramen, fracture
involving the mid-shaft of the humerus possess great danger in fracture healing.\textsuperscript{10}

**Number of Foraminas**

In the present study, nutrient foramen was present in 95\% of the humerus bone (out of 100 specimens) similar to studies done by Khan et al.\textsuperscript{[9]} (90.67\%), Muralimanju et al.\textsuperscript{[13]} (93.8\%), Yaseen et al.\textsuperscript{[17]} (89\%). In the present study, 91 specimen showed single foramen (91\%) and 4 specimen (4\%) showed double foramen.

</table>

In the present study, majority of the nutrient foramen was located in the anterior medial surface (66\%) followed by medial border (25\%). Majority of the study like Mansur et al.\textsuperscript{[12]} solank e et al.\textsuperscript{[14]} Yaseen et al.\textsuperscript{[17]} showed the nutrient foramen was present more commonly on the antero-medial surface when compared to other surface. According to Grays Anatomy 41\textsuperscript{st} edition, the nutrient foramen is situated a little below its mid-point on the anteromedial surface very close to the medial border.\textsuperscript{[15]} Ashish Ratwa 2019,\textsuperscript{[2]} stated that 73.61\% of the nutrient foramina were situated in the antero-medial surface comparable to the present study. Similarly other authors like Gopalkrishna et al (70.97\%),\textsuperscript{[17]} Yaseen et al (88.5\%),\textsuperscript{[17]} stated nutrient foramen of the humerus is more commonly present on the antero-medial surface.

Chandan Sintakala,\textsuperscript{[5]} reported 98.47\% of foramen directed downward and 1.53 \% directed horizontally. Kumar S et al.\textsuperscript{[10]} reported 99.54\% directed downwards and 0.46\% directed horizontally. Present study shows the similar result with 98.94\% of foramen directed downward which is comparable with the previous studies.

An understanding of the anatomical aspect of the nutrient foramen with its location and number is very important for orthopaediac surgeries such as open reduction and internal fixation, bone graft etc.\textsuperscript{[16]} Understanding of nutrient foramen is also very important for Anatomist for proper teaching the importance of nutrient foramen to first year MBBS students.

**CONCLUSION**

This study highlights the importance of nutrient foramen in humerus bone. It is important to note that humerus shows single foramen in majority of the specimen which is very important for its vascularity of the entire humerus bone. The vasculature of the humerus should be preserved in case of fracture humerus or other pathological condition for which the landmark and number of the foramen should be known.\textsuperscript{[11]}
