INTRODUCTION

Chronic suppurative otitis media (CSOM) is a disease of multiple aetiology and is well known for its persistence and recurrence, despite treatment. CSOM is a destructive disease with irreversible sequelae and can proceed to serious intra and extra cranial complications.[1] The microbiological flora of the middle ear varies and depends on the type of otitis media. In the acute form, the major organisms present are Haemophilus influenza, Streptococcus pneumonia, Pseudomonas aeruginosa and anaerobic bacteria.[2] CSOM has received considerable attention, not only because of its high incidence and chronicity, but also because of issues such as bacterial resistance and ototoxicity with both topical and systemic antibiotics.[3] The wide spread use of antibiotics has precipitated the emergence of multiple resistant strains of bacteria which can produce both primary and post-operative ear infections. The indiscriminate, haphazard and hayhearted use of antibiotics and the poor follow up of the patients have resulted in the persistence of low grade infections. The changes in the microbiological flora following the advent of sophisticated synthetic antibiotics have increased the relevance of the reappraisal of the modern day flora in CSOM, and there in vitro antibiotic sensitivity pattern is very important for the clinician to plan a general outline of treatment for a patient and can minimise complications that may require surgery for a chronically discharging ear.[3] The study of bacteriology and drug sensitivity is necessary to enable the treating family physician to plan the general management of CSOM and it is almost essential for the ENT surgeon to make the discharging ear dry for better results of myringoplasty and ossiculoplasty.[4] The objective of this study is to determine the aetiologic agents
and their antibiotic susceptibility pattern in CSOM patients for appropriate treatment.

MATERIALS AND METHODS

One hundred and fifty patients, who presented to the ENT Department from February 2022 to January 2023 with a history of chronic discharging ear, were prospectively studied. Two sterile cotton swabs were used to collect ear discharge from CSOM patients. Only those cases were selected who had not taken any treatment either systemic or local in the form of ear drops for the last seven days. One swab was used for performing Gram stain and KOH preparation and second one for culture. Culture was done on nutrient agar, blood agar, Mac-Conkey agar and SDA. The organisms were identified by culture characters, morphology, and pigment production, beta-haemolysis on blood agar, motility and conventional biochemical tests. Antimicrobial susceptibility test for all isolates was performed on Mueller-Hinton agar plate using Kirby-Bauer disc diffusion method. Antibiotic discs were procured from HiMedia Labs Mumbai. Results were interpreted using Clinical Laboratory Standards Institute (CLSI) guidelines.

RESULTS

Out of 152 swabs, 30 (19.7%) were sterile while 122 (80.2%) yielded growth of organisms. Isolation of bacteria was done in 119 (78.2%) ears while 3 ears revealed fungal growth as Candida albicans in two and Aspergillus flavus in one of the case. The most common organisms isolated were Pseudomonas aeruginosa 42 (36.5%) and Staphylococcus aureus 34 (29.5%) followed by other Enterobacteriaceae members like Proteus spp., Escherichia coli, Klebsiella and Citrobacter. Details of various isolates from CSOM samples are depicted in Table 1. No growth was observed in 30 (19.7%) samples.

Most sensitive antibiotic groups were Fluoroquinolones and Cephalosporin’s and least sensitive was Penicillin’s and Macrolides. Cephalosporin’s and fluoroquinolones showed maximum sensitivity with 97% & 100% and 76%, 83% sensitivity for Pseudomonas spp. and Staphylococcus aureus respectively.

DISCUSSION

CSOM is a condition of the middle ear that is characterised by persistent or recurrent discharge through a chronic perforation of the tympanic membrane. Untreated cases of CSOM can result in a broad range of complications. Thirty (19.7%) samples were sterile in the present study. This is in comparison with the results found by Kumar et al,[6] (4.39%) and Vijaya et al,[7] (5.28%), while Chakraborty et al.[8] (12.6%), Vijaya et al (17.6%),[7] and Fatma et al,[9] (16.9%) found higher percentage of sterile samples. This may be due to prior antibiotic therapy. All samples in the present study yielded single type of organism. Kumar et al.[6] and Fatma et al,[9] also reported 93.1% and 94% of monobacterial growth in their studies, respectively, while Vijaya (1998),[10] reported only in 51% of samples.

Our results show that active CSOM infection is mainly due to Pseudomonas aeruginosa (36.5%) and Staphylococcus aureus (29.5%). The third most commonly isolated organism, coagulase-negative Staphylococcus, may represent skin flora contamination, and not be a true pathogen. This finding is in tandem with the pattern of CSOM infection within the tropical region. It is seen that both Gram-positive and Gram-negative organisms are responsible for infection of middle ear. It is usually seen that Gram-negative rods outnumber the Gram-positive organism in CSOM. In the present study, Pseudomonas aeruginosa was the predominant organism followed by Proteus spp. These findings are in accordance with those of many previous investigators,[6,8,9,11,12,13] A H C Loy (2002),[13] Lakshminipathi and Bhaskaran (1965),[14] Gulati et al,[15] Ayyagari et al,[16] while Vijaya et al,[17] found Klebsiella as the predominant isolate in CSOM cases. The findings of predominant Gram-negative bacilli is consistent with many previous investigators,[6,8,11,12,18] Gulati et al,[15] Rajendra Kumar (1975),[19] Gulati et al,[20] Mishra et al,[21] while studies conducted by various investigators [Table 3,14,7,10,17,22] Singh and Bhaskar (1972),[23] Rao et al,[24] Rao and Reddy (1994),[25] Friedmann (1957),[26] found Staphylococcus aureus to be the most common causative organism,[1] which is the second common isolate in our study. All the pathogenic strains isolated in the present series were tested against various antibiotics Kumar et al,[6] and Chakraborty et al,[8] also reported 95.40% of resistance to amoxicillin among CSOM isolates. 40-50% of Pseudomonas aeruginosa isolates have shown resistance to piperacillin, ceftazidime, Ampicillin, but sensitivity was moderately good for Gentamicin, and ciprofloxacin. All other Isolates are sensitive to routinely used antibiotics. Amikacin was found to be the most effective drug followed by Gentamicin, Ciprofloxacin, and Cefoperazone. These findings are in accordance with those of Gulati et al,[20] and Mishra et al.[21] S. aureus was
fairly sensitive to erythromycin, gentamicin and ciprofloxacin. This is in comparison with the reports of Hegde et al,[12] and Goyal et al.[13] In the present study, gentamicin with fair susceptibility pattern is more effective in treating. 90% of isolates showed resistance to amoxicillin. Amp=Ampicillin; Amox-Clav=Amoxicillin-Clavulanic Acid; Macro=Macrolides; Amino=Aminoglycosides; Cepha=Cephalosporins; Floro=Fluoroquinolones.

CSOM as majority of pathogens in CSOM cases are susceptible to it. When used topically, gentamicin induced ototoxicity is rare.[12] When the results of various workers were compared, one fact became obvious that the bacteriology and antibiotic susceptibility pattern of CSOM has been changing from time to time. The strains of yesterday which were sensitive to Streptomycin, Tetracycline and Chloramphenicol no longer exhibit the old sensitivity pattern today. These drugs have been replaced by amino glycosides, quinolones and cephalosporin’s.[1]

Pseudomonas continues to remain supreme as a primary offender and poses problem for effective therapeutic control.[11] Staphylococcus aureus bear the inherent trait of resistance. In the era of antibiotics, the emergence of antibiotic resistance is becoming more common. Patient non-compliance is an important factor responsible for the development of antibiotic resistance. As soon as symptoms subside, many patients stop taking antibiotics before completion of therapy and allow partially resistant microbes to flourish. Such practice should be condemned strongly and patients should be educated to avoid the same.

For the antibiotics commonly available locally as topical eardrops, gentamicin and ciprofloxacin were shown to be the most effective, with good sensitivities for the commonly isolated organisms. With specific regard to the two most common pathogens in CSOM, Pseudomonas aeruginosa was found to be more resistant to commonly used antibiotics, while Staphylococcus aureus showed moderately good sensitivity to all antibiotics tested. Gentamicin eardrops thus appear to be an effective first-line topical antibiotic in the treatment of active CSOM.[13]

**CONCLUSION**

Knowledge of the pathogens and antibiotic sensitivity pattern responsible for CSOM and choosing suitable antibiotics according to susceptibility tests should guide the management of disease treatment and reduces intracranial and extra cranial complications with CSOM.
