Abstract

Background: Postpartum intrauterine contraceptive device insertion is an admirable family planning method which offered safe effective, long term and flexible contraception to women in the delivery setting. The rationale behind the study was to evaluate the clinical outcome of postpartum insertion of intrauterine contraceptive device in terms of safety and efficacy and to compare the two routes of insertion i.e. in vaginal deliveries and caesarean section.

Objectives: To study level of awareness among parturient towards PPIUCD. 2. To study safety and efficacy of PPIUCD insertion.

Materials & Methods: A Cohort of 200 women was selected as 100 vaginal and 100 caesarean deliveries with PPIUCD insertion and the study was conducted from the period of October 2022 to September 2023 in Andhra Medical College, Visakhapatnam. Outcome measures of safety were perforation, irregular bleeding, unusual vaginal discharge, and infection. Outcome measures of efficacy were pregnancy, expulsions, discontinuation, and incidence of coiled up/undescended strings.

SPSS software was used for data analysis and p value of less than 0.05 is considered statistically significant.

Results: In the present study only 38% (N=76) of the study sample were aware of the PPIUCD while the rest 62% were unaware. No serious complications such as pregnancy or perforation were encountered in our series. Most frequent complication stated in both the groups was excessive bleeding PV supported by pain in lower abdomen.

Conclusion: PPIUCD is an outstanding method to limit or space child births. It is suggested to a woman in a setting when she is highly inspired and genuinely needs it.

INTRODUCTION

In developing countries like India, many unplanned and undesired pregnancies end from non-use of contraception, most of which account to induced abortions. Continuation of these pregnancies is also related with greater maternal complications and adverse perinatal outcomes.[1] In India, 65% of women in the postpartum period have an unmet need of family planning.[1] Postpartum insertion of intrauterine contraceptive devices (I-PPIUCD) is a safe, private, and highly accessible choice for women who desire long acting reversible, efficient, coitus-independent, non-hormonal protection from pregnancy. It does not interfere with breast feeding and has few side effects, beginning during the critical postpartum period, when the women is highly encouraged for accepting a long term, reliable, feasible, safe and reversible contraception. At this time, the woman is even now hospitalized with the health care provider for the childbirth and leaves the hospital with an efficient contraceptive in place.[2] PPIUCD insertion is an exceptional opportunity to offer postpartum contraception to rural women having marginal access to medical care and infrequent and inaccurate postpartum visit because of socioeconomic reasons. Birth to pregnancy interval of less than 24 months is associated with increased risk of maternal mortality, induced abortion, and miscarriage.[2] Therefore, the recommended interval before attempting the next pregnancy is at least 24 months in order to reduce the risk of adverse maternal, perinatal and infant outcomes.[3] Hence, this prospective interventional study was dedicated to find out the safety and efficacy of PPIUCD insertion through the two routes i.e. vaginal deliveries and caesarean section.
MATERIALS AND METHODS

A prospective Cohort interventional study was conducted from the period of October 2022 to September 2023 in the Department of Obstetrics and Gynaecology in Andhra Medical College Visakhapatnam . Two hundred postpartum subjects after contraception counselling included in the study. All eligible antenatal subjects hospitalized for delivery were counselled for PPIUCD. Consent was obtained from those who opted for insertion of PPIUCD, they received CuT 380A. The study subjects were divided into two groups:

Group A: vaginal deliveries (100 cases).
Group B: intra cesarean (100 cases).

Post placental insertion was done by

Manual Technique
This technique is used only within 10 minutes following the delivery of placenta. In this period the cervix is still almost fully dilated. This accepts the passage of either forceps or the hand. After the active management of 3rd stage of labour is complete bimanual examination was performed to ensure empty uterine cavity. Implementing active management of third stage of labour is the first step for a safe IUCD insertion. IUCD pack was aseptically opened and CuT was held in right hand and slowly inserted through the cervix into the lower uterine cavity. CuT was slowly moved upwards until fundus of uterus can be felt. The hand over the fundus and CuT are approximated and then IUCD was left at the fundus and the hand was slowly moved along the lateral wall of the uterus taking care not to dislodge the IUCD, while stabilizing the uterus with the outside hand. The IUCD should be inserted prior to the IUCD, while stabilizing the uterus with the

Long ring forceps technique
Post placental insertion of IUCD by ring/Kelly's forceps after vaginal delivery is much less painful to the client. It is easier to perform if the client has a well contracted uterus and has benefited from AMTSL. With forceps insertion it is easier to the clinician to maintain appropriate infection prevention. Therefore, long sterile gloves or regular length gloves with a water impermeable apron are not required. During manual insertion, the IUCD may be accidental displaced into the lower uterine cavity or pulled out actively when the hand is withdrawn. This problem is less likely with forceps insertion because forceps are slimmer than a hand.

Trans Cesarean Insertion
Following a cesarean delivery after the uterine angles are secured massage the uterus until the bleeding subsides. Make sure that uterine cavity is empty and haemostatic. Place the IUCD at the uterine fundus manually holding it between the index and middle

finger or with a grasping instrument. Before stitching the uterine incision place the strings in the lower uterine segment near the internal cervical os. Prior to discharge post insertion counseling and advice was given to each woman. Discharge Card showing type of IUCD and date of insertion were given. Woman was told when to return for IUCD follow-up/PNC/newborn check-up (6 weeks). She was notified to return anytime, if she observes foul smelling discharge different from the usual lochia, lower abdominal pain especially if accompanied by not feeling well, fever and chills, feeling of being pregnant or suspicion that IUCD has fallen out.

RESULTS

As per table 1 among 200 deliveries done around 38% were aware about PPIUCD while 62% were unaware. This can further suggest the awareness levels towards PPIUCD was quite low as per current study. [Table 1]

As per table 2 a linear correlation was observed between the educated and uneducated women regarding awareness of I-PPIUCD. All graduate women were aware about PPIUCD. This shows education was significantly associated with awareness (p<0.05). [Table 2]

According to table no. 3 follow up percentage was not satisfactory. Only 30% came for the first follow up visit and 18% for the 2nd visit. Rests of the subjects were lost to follow up. [Table 3]

As per table 4 At the first follow up between 4-8 weeks, most common complication reported in both the groups was lower abdominal pain followed bleeding PV which was statistically significant (p<0.05). No case of perforation or pregnancy was reported during the study. At the second follow up between 12-16 weeks, the vaginal delivery cases reported more complaints of excessive bleeding PV and unusual vaginal discharge, while caesarean has lower abdominal pain. [Table 4]

As per table 5 In vaginal deliveries, the frequent reasons for PPIUCD removal were menorrhagia and discharge PV which could not be relieved by the conservative treatment. In cases of caesarean sections, the indications of removal were pain in abdomen, menorrhagia. The overall discontinuation rate was 29% in vaginal deliveries and 20% in caesarean section. [Table 5]

| Table 1: Distribution of Cases according to type of delivery and Awareness (N=200) |
|--------------------------------------|-----------|-----------|
| Type of delivery | Number | Awareness |
| | | Aware | Unaware |
| Vaginal | 100 | 36 | 64 |

DISCUSSION

In the present study the awareness level was 38%. Among those who were aware, maximum acceptance was seen in cases with secondary (81%) and higher education (100%). The awareness levels varied in different studies from 5.79% to 53.5%. In the present study 55.5% of the women were para-1, 35.5% were para-2 and 9% were para-3. In other studies women with one child accepting IUCDs varied from 46.5%–73.17%, women accepting IUCD having two or more children varied from 35.76%–48.3%. The acceptance rates in different studies varied from 9.4% to 48.3% depending on their education status. In a report released by WHO in 2006, healthy timing and spacing of pregnancies has a direct effect on maternal health and new-born outcomes. In countries with high birth rates, about 32% of all maternal deaths and over one million deaths of children below 5yrs could be prevented by healthy timing and spacing of pregnancies. This finding indicates a positive maternal health outcome in well-spaced pregnancies, irrespective of the contraceptive used. It is noteworthy that there were no serious complications in this study. 15% (N=30) cases had menorrhagia, of these IUCD had to be removed in 14 cases as they did not respond to treatment given. Incidence of menorrhagia varied from 11.5%–27.23% in various studies. In the present study pain abdomen was reported in 18.5% cases (N=37) in this study. Pain was reported more in cases of caesarean sections (N=21) compared to vaginal deliveries (N = 16). Similar resulted were reported in other studies. There were no cases of perforation or pregnancy in the present study. This is in accordance with the other studies. Absence of uterine perforation and low incidence of infection are strong indicators of safety. Post-partum IUD insertion is common in several countries.

CONCLUSION

This study concludes that post-placental IUCD is an effective method of contraception. In the current region where access to care is limited and postpartum care is often infrequent, this level of programmatic achievement can be considered as high success. Despite very poor awareness among these women, the acceptance was high. It demands for developing strategies to increase public awareness of the PPIUCD through different media sources. It is also important to impart training on PPIUCD to increase knowledge and skills among health care providers. This will aid in promoting PPIUCD use besides reducing expulsion rates.
